ABSTRACT

The transition to parenthood is a difficult and stressful time for many couples, and those who become parents in their teens will most likely experience stress and challenges. The objective of this review is to scrutinize evidence related to the experiences of the transition to parenthood in teenage married couples. The scoping review method used was the Arksey & O’Malley framework consisting of 5 stages including identification of the PICO framework, identification of relevant articles, searching for articles from databases such as Science Direct, Pubmed, and Willey, selecting in Prisma Flow Charts, conducting Critical Appraisal on articles, doing data charting, compiling, summarizing, and reporting the results. Based on the search results from the databases, 11 articles were obtained. Of the 11 articles, an assessment was carried out and all articles got a grade of A, 4 articles with the quantitative method and 7 articles with the qualitative method. Furthermore, 3 themes were identified, namely social support, psychological impact, and barriers. The conclusion of the study found a gap in the results of review articles in developed countries and developing countries. In developed countries, the results of review articles tend to focus on psychological problems in the transition to parenthood. The adolescent parents feel pressured and are not ready to become new parents, causing stress and depression when becoming new parents. In contrast to developing countries, psychological problems in the transition to parenthood tend to focus on social support and barriers to becoming new parents.

ABSTRAK

INTRODUCTION

According to the World Health Organization (WHO), adolescents are defined as young people aged 10-19 years or those in the transition period between childhood and adulthood (WHO, 2017). The highest number of teen marriages occurs in African and Southeast Asian countries (Yastirin, 2019). Indonesia is the 37th country out of 158 countries with the highest teen marriage rate in the world, while according to ASEAN (Association of South East Asia Nations), Indonesia is in second place after Cambodia in the highest teen marriage rate with a total of 36% (Mugni, 2019). In response to this, the Indonesian government has attempted to formulate prevention strategies, one of which is by ratifying the Marriage Law No. 16 of 2019 regarding the age limit for child marriage that marriage is only permitted if the male and female parties are 19 years old (Perpres, 2019). This teen marriage has also been proven to have consequences for teenagers, one of which is teenage pregnancy with the consequence that they turn into parents at an immature age (Farida et al., 2019). The transition to parenthood is a difficult and stressful time for many couples, and those who become parents in their teens will most likely experience stress and challenges (Jones et al., 2018).

Factors that cause marriage in adolescence can occur due to the poor family economic problems. No good knowledge regarding the bad consequences of marriage in adolescence and knowledge of reproductive health were recognized (Hadiono.AF, 2018). Psychological factors of the transition to parenthood in teenage married couples include the unpreparedness of teenagers to be responsible in terms of morals, and they often face mental shocks due to still having mental tendencies that are inclined to be emotionally inconsistent or unstable (Ratnawati, A, 2017). The impact of marriage in adolescence in going through the transition to parenthood is the psychological matters such as anxiety and stress caused by the inability of adolescents to accept the changes and new roles in a marriage, and they are not yet fully mature for parental responsibilities (Tahir.NQ, 2020).

Family social support plays a prominent role in improving parenting competence by providing positive resources and encouragement during the transition to being a caring, responsible and productive young father (Uengwong sapat, 2020). In dealing with problems that occur in adolescents, especially in teen marriages, the government has made various efforts by establishing the Youth Care Health Service Program (PKPR) (Muntamah et al., 2019). Married adolescents who become parents assuredly have special needs and problems that need mutual attention. Therefore, the latest evidence is needed as information for stakeholders regarding the needs and expectations of married adolescents (Kurniawati & Astuti, 2020). The objective of this scoping review is to conduct a review of the experiences of the transition to parenthood in teenage married couples.

METHOD

This research method is Scoping Review, which is a structured view used to interpret research problems based on the truth, research, origins, existing data and information. In this Scoping Review, the process includes grouping the articles, formulating research questions, identifying relevant literature sources, selecting the literature, mapping the research data, compiling research results, summarizing research results, and reporting discussion results.

The inclusion criteria for this scoping review were articles published in English and Indonesian, articles published from 2011-2020, articles published in the original form, articles published in the full-text form, documents/reports/draft and policies/guidelines from WHO/Organization, and articles published to discuss the transition to parenthood. Meanwhile, the exclusion criteria for this scoping review were opinion articles, letters or book reviews. In search of scoping review articles, this study utilized the Science Direct, Willey, and Pubmed databases, and the keywords used to search the literature are: teenage pregnancy OR adolescent pregnancy AND adolescent parenthood AND Support AND Psychological AND Transition AND Experience.

Based on the figure above, the research articles that the researchers imported into Mendeley and screened were 1,230 articles which were able to help answer the research questions. Then, of the 1,230 articles obtained, 37 duplicate articles were removed, leaving 1,193 articles. After that, the articles were screened or filtered, resulting in 682 selected articles. Furthermore, article elimination was conducted based on the title and abstract with the results of 359 articles excluded due to their irrelevance, leaving 286 relevant articles. Then, a full-text reading of articles was carried out with the results of 41 articles, and 31 of 41 articles were excluded with 9 articles that were not in accordance with the research objectives and 22 articles that contain errors in the population. Thus, the total articles to be analyzed using scoping review are 11 articles, and the articles were assessed using Critical Appraisal with Hawker attachments.

**RESULTS AND DISCUSSION**

The results of this scoping review were obtained through data extraction on articles that have been selected by categorizing the title, year, research objectives, methods, number of samples, and research results. Hence, the results of article mapping are obtained, namely:

### a. Year of publication

From 11 articles, the year of publication obtained includes 2 articles in 2015, 2 articles in 2016, 1 article in 2017, 1 article in 2018, 1 article in 2019, 2 articles in 2020 and 2 articles in 2021.

b. Method

The methods obtained in 11 articles include 1 article in quantitative study with HLM approach, 1 article in longitudinal study, 1 article in cross-sectional study, and 1 article in correlational study and Chi square test. Besides, the methods obtained also include 2 articles in qualitative method with a grounded theory approach, 1 article in TCAC, 1 article in deductive qualitative study with secondary data, 1 article in qualitative study with a purposive sampling technique, 1 article in a longitudinal approach, and 1 article in qualitative study with purposive and snowball techniques.

c. Country

In the articles collected, the research was carried out in several countries including developing countries and developed countries. In developing countries, such as in the Asian continent, it was found 1 article from Thailand, 1 article from Jordan, and 2 articles from Indonesia. On the other hand, it was found 1 article from one of developing countries in the European continent, namely Sweden, and 1 article from Australia. It was also found 1 article from one of developed countries in Asia, namely Singapore, 3 articles from USA, one of developed countries in American continent, and 1 article from one of developed countries in the European continent, namely Portugal.

d. Grade

Based on the results of the Critical Appraisal conducted in this scoping review, the scores are categorized according to the grade of the article. After the assessment, all articles in this study received grade A with good quality.

e. Theme

Based on the results of the scoping review, the research are categorized into three research themes, namely family support provided for couples transitioning into adolescent parents, the psychological impact that occurs on couples transitioning into adolescent parents, and the barriers during the transition to adolescent parents.

The theme mapping carried out by the authors is classified as an interesting study from article reviews:

<table>

</tr>
</tbody>
</table>

1. Social support provided for couples transitioning into adolescent parents

a. Family support

Study by (Morawska et al., 2018) confirmed that the transition to parenthood affects the individual level of both mother and father because family support in the process of receiving early caregiving support is a consideration in self-acceptance. Supportive families are considered beneficial for adolescent couples who turn into parents in terms of material, emotional, and psychosocial support (Mrayan et al., 2016).

This is in line with research by (Sriyasak et al., 2016) that adolescent parents reported receiving support from their families in the form of emotional, physical, financial, material, and informational support.
b. Health worker support

According to research by (Morawska et al., 2018), parents really need support from doctors. Most of them also accessed support from pediatricians and child health nurses. Parents indicated that they felt very satisfied with the support provided by health workers to find out information during the transition to become new parents. The role of health can share experiences obtained when being a parent and share mental, emotional knowledge and readiness to become parents (Barimani et al., 2017).

This is in line with research by (Muzik et al., 2016) that various forms of support emerge in physical and mental health through support for pre- and postnatal medical care, i.e. there is a clear need for accessible community-based obstetrics and gynecology services.

2. Psychological impact on couples transitioning into adolescent parents

a. Stress during the transition to being a new parent

The transition to parenthood is considered a major life transition event that can be awfully stressful for new parents (Chen et al., 2021). The transition to new parenthood can involve preparation, adaptation, and transfer to adult services in a multifaceted process where medical, educational, vocational, and psychosocial needs play a significant role (Wright et al., 2017).

Severe anxiety can interfere with daily activities and affect relationships and major lifestyle changes. Roles can affect relationships by the increasing level of stress and affect the lifestyle of married couples who are becoming parents (Martins, 2019).

b. Depression during the transition to being a new parent

In the transition to being new young parents, they are very vulnerable to poor mental health, and young mothers experience higher rates of depression (Sipsma et al., 2016). The increased stress may also occur due to the natural transition from adolescence to adulthood, during which time the young father may have taken on additional responsibilities to care for his family. The symptoms of depression occurring among young fathers may increase after postpartum.

This is in line with research by (Coelho et al., 2013) regarding depression which tends to be interpreted as the emergence of pregnancy in a pessimistic manner so that it is not in tune with the mood. The birth of a child is an unwanted event, and life events during pregnancy are full of stresses that increase the risk of depression.

3. Barriers affecting couples transitioning into adolescent parents

a. Lack of knowledge factors can affect the barriers of couples transitioning into adolescent parents

Barriers can be identified in parents’ knowledge about parenting practices, and lack of information about breastfeeding demands is an obstacle (Barimani et al., 2017). Barriers occurring in adolescent parents make them find it difficult in their new role. Adolescent parents need guidance to become a partner of adolescent parents and to deal with the pressures of marriage and their responsibilities in life as parents (Astuti, Hirst, et al., 2020).

This is in line with previous research which explained that the barriers often occurring in the transition of adolescent parents are such the emotional burden exacerbated by their disrupted and stopped education, making it difficult to get direct and long-term jobs (Astuti et al., 2021).

CONCLUSIONS AND SUGGESTIONS

The conclusion of this scoping review found a gap in the results of review articles in developed countries and developing countries. In developed countries, the results of review articles tend to focus on psychological problems in the transition to parenthood. The adolescent parents feel pressured and are not ready to become new parents, causing stress and depression when becoming the new parents. In contrast to developing countries, psychological problems in the transition to parenthood tend to focus on social support and barriers to becoming new parents. The social support is what they really need when they are transitioning to parenthood, while the barrier is their lack of knowledge which makes them worry about about becoming new parents in their teens.

Suggestion for further research is to be able to develop and reproduce references and good knowledge that researchers can get when conducting research in the form of scoping review so that they can be used as further qualitative research.

ACKNOWLEDGEMENT

The authors would like to thank the Midwifery Masters Study Program, Faculty of Health Sciences, Universitas ‘Aisyiyah Yogyakarta, which has provided facilities in the preparation of this manuscript and all parties involved in assisting the completion of this research.

ETHICAL CONSIDERATIONS

This type of research is a scoping review, so the researchers do not register an ethical review.

Funding Statement

- The authors did not receive support from any organization for the submitted work.
- No funds were received to assist in the preparation of this manuscript.
- No funds were received to conduct this research.
- No funds, grants or other support were received.

Declaration of Conflict of Interest

The authors declare that no conflict of interest was found in the research or preparation of the manuscript.
